

Orthodontics Penticton

If you're seeking to reposition your jaw, as well as rectify and line up jagged teeth, then orthodontics may be a good alternative to take into consideration. Out of line or twisted teeth are a lot harder to clean up and keep fresh and tend to be more vulnerable for developing tooth decay and periodontal disease. Furthermore, poorly aligned teeth can put added strain on the biting muscles that might induce severe headaches, neck, back, shoulder pain, or TMJ ailments. Orthodontics may be used to correctly arrange the teeth to help increase the visual appeal of your teeth.

Oral health issues like overbites take place when the upper arch teeth project past the lower arch teeth; hence, the patient requires immediate orthodontic treatment. An underbite is the opposite of an overbite, whereby the lower arch teeth project past the upper arch teeth. A crossbite happens when the top and lower teeth do not effectively come together and a wide open bite comes about when places between the biting surfaces on the front or side of teeth, when the rear molars bite together. Other troubles that may demand orthodontic treatment consist of spacing, crowding and a mislaid midline. Spacing comprises holes or breaks between the teeth that might have been a consequence of losing teeth or that your particular teeth are far too small to fill up the mouth. Crowding of the teeth happens when there is not sufficient room on the dental ridge for all of your teeth. Finally, a misplaced midline occurs when the upper and lower arch teeth do not align naturally in the front.

Orthodontic treatments may help a patient fashion and maintain a healthier mouth, while enhancing the overall appearance and are able to augment the lifespan of the teeth.
