

Laser Gum Therapy Penticton

Oral health Lasers have been used more frequently in dentistry over the last couple decades. They may be used to take care of many oral health issues including periodontal tissue refashioning, cementing tooth fillings, removing cavities and decay, and teeth bleaching. Also, lasers can be used in the removal of bacteria from the pockets and spaces of the gums.

One of the advantages to using lasers is that they eliminate the requirement for the dentist's drill which may lessen clients' fears about receiving oral health care applications. Diode lasers and the Waterlase[®] system lasers provide a therapy option that is nearly painless, thus removing any requirement for anaesthesia.

Other advantages to laser dentistry include no more irritating high frequency drilling noises and a decrease of bleeding throughout gum treatment as the laser cauterizes blood vessels, which may eliminate bleeding and lessen the incidents of infection. Another positive result of laser therapy is the capability of the laser to minimize bacteria levels for long term protection. Also, the precision of the laser can preserve healthy tissues during treatments and procedures and oral health care professional can treat developing tooth issues before they have a chance to proliferate and bring about damage.
